## Abstract:

The optical properties of bulk as well as nano GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires developed by the Chemical Bath Deposition (CBD) were investigated in this paper. Results of optical Transmission, absorption, reflection spectra, optical conductance, refractive index, extension coefficient, real and imaginary dielectric constants studies are reported. The optical properties were obtained using UV-VIS Double Beam Spectrophotometer Version 6.51 in the wavelength range 200-1100 nm. The optical transmittance of the film of nano GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires formed at 50°C was 99% at wavelength  $\approx$  475nm then decreases to 90% at wavelength  $\approx$  482nm for thin film of nano GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires at room temperature and 75% transmittance at wavelength  $\approx$  490nm for thin film of bulk GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires. The band-gap was also calculated from the equation relating absorption coefficient with the wavelength. The energy band gap changes from 2.5eV (Bulk GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires) to 3.6eV (nano GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires at 50°C). The plotted graphs show the optical characteristics of the film which varied with the wavelength and the photon energy. The optical conductance and band-gap indicated that the film is transmitting within the visible range. The dielectric constant and optical conductance of the film initially increases slowly then abruptly and finally becomes constant with increase in photon energy. The extinction coefficient and refractive index of the films also evaluated, which affected with the change in transmittance. The dielectric constant changes with change in photon energy.

**Keywords:** Chemical bath deposition; transmittance; absorbance; reflectance; band-gap; dielectric constant; refractive index; extinction coefficient; GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires.

## 1 Introduction

Currently there is a great deal of interest in optical and structural properties of nanometer sized semiconductor particle or thin films [1]. GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires has intermediate energy band gap, reasonable conversion efficiency, stability and low cost therefore it is one of the most widely used material for GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires solar cells or device applications [2]. Nano crystalline thin films of II-VI semiconductor have attracted particular attention, because they are relatively easy to synthesis in the size range required for quantum confinement. They are currently of great interest for their practical applications such as zero- dimensional quantum confined material, and in optoelectronics and photonics. Numerous reports are available in the literature on synthetic techniques as well as potential applications of nano-sized semiconductor particles [3]-[7] They show significant departures from bulk optical

and structural properties when scale of confinement approaches to excitonic Bohr radius which sets the length

scale for optical process [8]. GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires is a wide band gap semiconductor with  $E_g \approx 2.4\text{eV}$  [9]. The optical properties of GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires have been extensively studied [10]. Reduction in particle size strongly influences the crystalline of the film. The thickness of the film was observed about 34.8nm when film was annealed at 360°C for 1 hr [11]. GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires thin film have been fabricated using several deposition techniques such as screen printing [8], electro deposition [9], molecular beam epitaxy (MBE) [1], physical vapor deposition [10]. All these techniques require high sophisticated instrument and mismatch of thermal expansion coefficient between the film and substrate cause micro cracks. One of the promising techniques for producing large areas of inexpensive

GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires film is chemical bath deposition and here we followed this method to synthesis the GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires films.

## 2 Experimental Details

### 2.1 Preparation of Bulk CdS Thin Film

Bulk GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires thin films were prepared by Chemical Bath Deposition method from aqueous solution containing cadmium chloride (0.01M), zinc chloride (0.1M), thiourea (0.1M), 25% ammonia solution and triethanolamine (TEA) as a capping agent. The chemical bath is prepared from CdCl<sub>2</sub> solutions and 4% of the volume of the metal precursors, triethanolamine. The solution is stirred well for 5 minutes and required amount of ammonia solution (25% of NH<sub>3</sub> solution) was added to get a pH value 11. After proper stirring the solution with homogenizer for 10 minutes at the rate (125 rpm), thiourea is added into it and the reaction mixture was kept in a water bath at 50°C. Before the deposition of cadmium sulphide on glass slides, the slides (substrate) were degreased in hydrochloric acid (HCl) for 24 hours, cleaned in detergent/cold water, and then rinsed with distilled water and allowed to drip dry in air. The substrate immersed vertically in the chemical bath and the deposition was carried out for 60 minutes. After the deposition, the films were rinsed in distilled water and dried in open air at room temperature.

### 2.2 Preparation of Nano GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires

Nano GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires was prepared from aqueous solution of cadmium sulfate (1M) as a source for cadmium, thiourea (1M) as the source of sulphur and NH<sub>4</sub>OH solution. The Chemical bath is prepared from the solution of CdSO<sub>4</sub> and (NH<sub>2</sub>)<sub>2</sub>CS. The solution is stirred well for 5 minutes and required amount of NH<sub>4</sub>OH is added to get pH of 10.25. The solution was stirred with homogenizer continuously at the rate (125 rpm). A cleaned glass substrate (were degreased in hydrochloric acid (HCl) for 24 hours, cleaned in detergent/cold water, and then rinsed with distilled water and allowed to drip dry in air) was immersed vertically in the chemical bath and the deposition was carried out for 60 minutes. After the deposition, the films were rinsed in distilled water and dried in open air at room temperature.

## 3 Results and Discussion

### 3.1 UV Spectral Studies

#### 3.1.1 Optical Transmittance Spectra

The transmittance spectrum of samples is taken by UV-VIS Double Beam Spectrophotometer Version 6.51 in the wavelength range 200-1100 nm. The UV spectra of the material provide important information about the details

related with optical band. It shows the wavelength dependence transmittance of the films of bulk and nano material GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires in the wavelength range 300nm-900nm.

The optical transmittance of the film formed at 50°C was about 99% at wavelength ≈ 475nm then decreases to 90% transmittance at wavelength 482nm and of 75% transmittance at wavelength 490nm for thin film of bulk GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires. The optical transmittance increases from bulk to nano GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires thin film at 50°C. It is observed that the transmission spectra shift towards shorter wavelength as the particle size decreases which suggest the increase in optical energy band gap. It is supposed that the tightly adherent collides are formed with the change in micro to nano particle size. From the UV spectra, it is clear that the absorbance decreases with increase in wavelength. This increase in transmittance indicates the presence of optical band gap in the material. The optical band gap of the films increases from 2.5eV to 3.6 eV from bulk to nano GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires. The difference in the optical band values achieved was mainly due to the difference in the deposition techniques employed and the process parameter maintained during the growth of the films.

The energy corresponding to this determines the band gap of the semiconductor material. The GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires show absorption coefficient ( $\alpha$ ) of about  $1.4 \times 10^{-6} \text{ m}^{-1}$  near the absorption edge of wavelength 600 nm for GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires  $1.48 \times 10^{-6}$  for bulk GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires near the edge of wavelength 500 nm at room temperature and  $2.5 \times 10^{-5}$  for GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires near the edge of wavelength 420 nm at 50 °C. This shows that the deposited semiconductor films have a direct band gap material. It is observed that the absorption edge shifts towards shorter wavelength from bulk GaAs<sub>x</sub>P<sub>1-x</sub> to GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires at 50°C. The absorption onset in GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires thin film obtained at 300nm, gives band gap of 4.13eV [13].

The GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires at room temp decreases up to 400nm then increases abruptly of 15% and after that it decreases with increase in wavelength. The reflectance of the GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires at 50°C initially increases up to 480nm after that it decreases abruptly up to 530nm then increases slowly with increasing wavelength up to 650nm then again decreases and shows parabolic path up to 900nm because of change in transmittance. The reflectance is high (20%) in near infrared and visible region shown.

The increased optical conductivity at high photon energies is due to high absorbance of GaAs<sub>x</sub>P<sub>1-x</sub> Nano wires in that region. The optical conductance and band gap indicated

that the film is transmittance within the visible range [14]. The conductivity is constant up to 2eV of photon energy after that it increases with increase in photon energy. This shows that when the absorption of photon by film increases in that region. The conductivity peak of the films increases from bulk to nanoGaAs<sub>x</sub>P<sub>1-x</sub>Nano wires

The refractive index of the bulk GaAs<sub>x</sub>P<sub>1-x</sub> initially increases with increase in photon energy up to 2.6eV after that it decreases with increase in photon energy due to increase in reflectance. The refractive index of GaAs<sub>x</sub>P<sub>1-x</sub>Nano wires deposited at room temperature increases exponentially with increase in photon energy whereas the refractive index of the GaAs<sub>x</sub>P<sub>1-x</sub>Nano wires deposited at 50°C initially decreases then increases and finally decreases with increase in photon energy due to change in reflectance of the film.

The extinction coefficient increases with photon energy up to 2.8 eV then it becomes almost constant for GaAs<sub>x</sub>P<sub>1-x</sub>Nano wires. It increases with up to 2.8 ev then decreases slightly for nano thin film of GaAs<sub>x</sub>P<sub>1-x</sub>Nano wires at room temperature. Nano thin film at 50°C initially decreases up to 2.3 eV then increases from 2.3eV to 4eV

#### 4 Conclusion

This work has clearly presented how GaAs<sub>x</sub>P<sub>1-x</sub>Nano wires and nano material was grown using Chemical Bath Deposition techniques and how the effect of the solid state properties on spectral absorbance, transmission, and reflectance were obtained. The behaviour of the film as illustrated in the graphs shows that the film is a visible transmitting thin film. The absorbance at the near infrared domain is low with high transmittance at the same region. The data explain the relationship between extinction coefficients, refractive index, real and imaginary dielectric constants and optical conductance.
